Document type: JOURNAL ARTICLE English Abstract

JOURNAL ANNOUNCEMENT: 9208

Subfile: INDEX MEDICUS

A five-year old boy was the product of a 40 week pregnancy by vertex presentation complicated only by threatened abortion at approximately 8 weeks gestation. Apgar score was 5 after one minute. At birth he was noted to have a generalized hypotonia associated with facial diplegia, small mandible, weak suck and swallow reflexes. Admission examination revealed small mandible, mask-like facial expression and mild mental retardation. Cranial nerve examination showed bilateral blepharoptosis and facial nerve palsies. Pupil reflexes were normal, but corneal reflexes were impaired bilaterally. Diplopia due to the left abducens nerve palsy was suggested. There was no atrophy of the **tongue**. Motor tone, strength, and deep tendon reflexes were normal. A normal 46 XY karyotype was present. The other clinical and laboratory findings were normal. MRI of the brain was unremarkable. The characteristics of electrophysiological studies were summarized as follows: 1) Auditory brainstem evoked responses demonstrated waveforms IV-V were abnormal because their amplitudes were less than 30% of wave I bilaterally. 2) Somatosensory evoked potentials documented by central conduction times from cervical region to sensory cortex were prolonged on both sides. 3) Facial nerve conduction velocity was calculated by evoked EMGs of the mentalis muscle electrically stimulated at two distal points over the marginal mandibular branch. MCV of the left side was reduced (34.2 m/sec). 4) The amplitude of the facial muscle potentials evoked by facial nerve stimulation was reduced on both sides. 5) Blink reflex responses documented by the latency difference of R1 responses between the two sides were prolonged. Primitive neuroectodermal tumor (neuroepithelioma) of spinal nerve root
-- Report of an adult case and establishment of a cell line.

Ishikawa S; Ohshima Y; Suzuki T; Oboshi S

Acta Pathol Jpn (JAPAN) Mar 1979, 29 (2) p289-301, ISSN 0001-6632

Journal Code: 1NE

Document type: JOURNAL ARTICLE

JOURNAL ANNOUNCEMENT: 8103

Subfile: INDEX MEDICUS

A case of primitive neuroectodermal tumor arising in the cervical nerve root of a 28-year-old man is presented. Histologically, the tumor was characterized by proliferation of primitive neuroectodermal cells and formation of numerous Homer-Wright type rosettes. A cell line (Nagai line) was established from the tumor. Electron microscopic examination of Nagai cells revealed numerous microrosette formation with microvilli-like cytoplasmic processes projecting into the central lumina. Neurosecretory granules appeared in the cytoplasmic processes when Nagai cells were treated with dibutyryl cyclic AMP. Primitive satellite cells which completely surrounded other tumor cells with their **tongue**-like slender cytoplasmic processes were also found. Histogenesis of this unique tumor was discussed comparing with the neuroblastoma of sympathetic nervous system, medulloblastoma of the central nervous system, and with the tumors induced by Adenovirus type 12 in animals. It was concluded that the tumor was neuroepithelioma derived from a primitive **stem** cell of **neural** crest origin which possesses the bipotency to differentiate toward either neuroblastic or neurilemmal line.

Proliferation, cell death, and neuronal differentiation in transplanted human embryonal carcinoma (NTera2) cells depend on the graft site in nude and severe combined immunodeficient mice.

Miyazono M; Lee VM; Trojanowski JQ

JOURNAL ANNOUNCEMENT: 9511

Subfile: INDEX MEDICUS

BACKGROUND: Embryonal carcinoma cell lines have been used to study the induction and progression of tumors, the mechanisms governing lineage commitment in the central nervous system, and the developmental biology of neurons and glia. Here, we have used a human embryonal carcinoma cell line (NTera2/cl.D1 or NT2 cells) that resembles **neural progenitor** cells to study how an in vivo environment influences and regulates the fate of these cells. EXPERIMENTAL DESIGN: To understand the mechanisms that coordinately regulate the proliferation, death, and differentiation of NT2 cells, we examined these processes by transplanting human NT2 cells in the brains and **peripheral tissues** (liver, muscle) of immunodeficient mice. RESULTS: We demonstrate that the proliferation, differentiation, and death of NT2 cells were modulated by the anatomical site into which the NT2 grafts were implanted. The NT2 cells continued to proliferate and undergo cell death but showed a very limited capacity to differentiate into neurons after implantation into the subarachnoid space and superficial neocortex. At this site, the NT2 cell grafts rapidly formed bulky tumors that were lethal within 70 days postimplantation. Further, NT2 cell grafts in the lateral ventricles, liver, and muscle behaved in a similar manner. In contrast, NT2 cells implanted into the caudoputamen ceased proliferating and showed no evidence of necrosis or apoptosis after postimplantation survival intervals of more than 20 weeks. This occurred in parallel with the progressive differentiation of large numbers of NT2 cells into postmitotic, immature, neuron-like cells. CONCLUSIONS: These results suggest that signal molecules or other "cues" (e.g., cell-cell contacts) capable of regulating the proliferation, death, and differentiation of human NT2 cells are biologically active in the adult mouse caudoputamen. Thus, the transplantation of human NT2 cells into the central nervous system of immunodeficient mice may serve as an in vivo model system for studies of the formation and re-modeling of the developing central nervous system.
